14. ABSTRACT <p>This report is the application of morphological image techniques to the energy detection scenario of signals in the RF spectrum domain. The algorithm automatically establishes a detection threshold based on the data of the RF spectrum measurement. Initially, a modified watershed transform was applied to form an envelope of the spectral data. Then a morphological “opening” operation was applied to the spectral envelope data to establish the noise floor. Using this noise floor estimation, an energy detection threshold was determined.</p>

Preface

Energy detection in the RF spectrum is the most basic technique for signal detection. Typically, this requires establishing an energy detection threshold based on a noise-only condition (i.e., no signal present in the RF spectrum). An investigation of morphological image processing techniques was successful in automatically generating an energy detection threshold based on the RF spectrum data without the requirement of having RF spectrum of noise only condition.

The technique of “opening” was very successful in determining an energy detection threshold for the RF spectrum with signal and noise-only environments. A second energy threshold detection algorithm was examined with the addition of a semi-disk structure applied to the RF spectrum. During the development of these automatic energy detection threshold generation algorithms, the watershed transform proved to be a good candidate to apply to the RF spectrum prior to the application of the opening technique. This is the third of 5 reports that detail the energy detection techniques examined with the recorded RF spectrum measurements.¹⁻⁴

1. Introduction

Energy detection is the simplest method of detecting a signal in the frequency spectrum. When doing so, a comparison is made between the frequency spectral component energy and a detection threshold level. Knowledge of the frequency spectrum is usually necessary to establish this detection threshold level. Various methods can be used to determine the detection threshold level, such as establishing the system noise statistics offline and setting the threshold for a given probability of detection versus probability of false alarm.

The goal of this study was to develop an algorithm that can analyze the frequency spectrum and establish a threshold value based on the spectral components. The automated processing employs techniques from image processing and statistical analysis. A combination of techniques from these 2 areas resulted in an algorithm for determining a detection threshold level. In an earlier evaluation, the morphological filter processing successfully determined the detection threshold level. In this evaluation, a modified watershed transformation is applied to the RF spectral data prior to the morphological filtering process. A reduction in false alarms was obtained.

2. Data Collection and Statistical Summary

The local RF spectrum was measured in 2013 on the rooftop of building 204 at the US Army Research Laboratory's (ARL's) Adelphi location. An Agilent N9342CN spectrum analyzer and a Discone Antenna was used to collect RF spectrum data. This spectrum analyzer was operated under the control of a Labview software program to acquire and store data with different resolution bandwidth (RBW) from 1 KHz to 1 MHz.

These data files represent various sizes of RF spectral coverage from 10 MHz up to 4 GHz. The number of data files for each spectral band varied. The larger RBW files were acquired over seconds of data acquisition time versus the small RBW files. Small RBW provides fine spectral resolution, but it has impact on data acquisition time for spectral coverage and data size. Depending on the RBW and spectral coverage, a data file could require a few hours of acquisition.

Table 1 summarizes the data collection measurements files. The RF spectral bands covered the spectrum from 10 MHz up to 4 GHz. In general, various spectral bands were measured with 4 RBW configuration. Data file size is inversely proportional to the RBW. Data file size is proportional to the spectral band coverage. The data size varied from approximately 1 KSample to 4 MSample data points per file.

Table 1 Summary of the RF spectrum collection

Spectral band coverage	Number of RBW measurement	RBW
1.1–1.6 GHz	4	1 kHz, 10 kHz, 100 kHz, 1 MHz
2–3 GHz	4	1 kHz, 10 kHz, 100 kHz, 1 MHz
3–4 GHz	3	10 kHz, 100 kHz, 1 MHz
4–6 GHz	3	10 kHz, 100 kHz, 1 MHz
10 MHz–1 GHz	4	1 kHz, 10 kHz, 100 kHz, 1 MHz
10 MHz–2 GHz	4	1 kHz, 10 kHz, 100 kHz, 1 MHz
10 MHz–3 GHz	4	1 kHz, 10 kHz, 100 kHz, 1 MHz
10 MHz–4 GHz	4	1 kHz, 10 kHz, 100 kHz, 1 MHz
100 MHz–1 GHz	1	100 kHz

3. Statistical Processing

3.1 Statistical Analysis

Statistical analysis is the mathematical science dealing with the analysis or interpretation of data. The data analyst uses a few straightforward statistical techniques as a means of summarizing the collected data. These statistical techniques are under the area of descriptive statistics, which is a methodology to condense the data in quantitative terms.

In commercial prognostics and diagnostic vibrational monitoring applications, statistical techniques that are mainly used for alarm purposes in industrial plants are the statistical moments of order 2, 3, and 4. The probability density function (PDF) of the vibrational time series of a good bearing has a Gaussian distribution (also known as a normal distribution), whereas a damaged bearing results in a non-Gaussian distribution with dominant tails because of a relative increase in the number of high levels of acceleration. These techniques can be applied to the RF spectral data with a different interpretation of the results.¹

3.1.1 Moments

If these moments are calculated about the mean, they are called central statistical moments. The first and second moments are well known, being the mean and the variance, respectively. These are analogous to the first and second area moments of inertia with the area shape defined by the PDF. The third moment is termed

skewness and the fourth moment is termed kurtosis. The general equation for the order of moment is as follows:

$$M_p = \frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^p.$$

where p is the order of the moment,

N is the number of data value,

i is the index of the data value, and

\bar{x} is the mean value of the data set.

3.1.2 Mean

Mean is the most common measure of a statistical distribution. In this case, mean is the arithmetic average for a set of measurements.

$$\bar{x} = \mu = \frac{1}{N} \sum_{i=1}^N x_i.$$

3.1.3 Variance

Variance is a measure of the dispersion of a waveform about its mean—also called the second moment of the measurements.

$$\sigma^2 = \frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2.$$

3.1.4 Standard Deviation

Standard deviation is a measure of the variation of a set of data values. The standard deviation is defined as the square root of the variance moment.

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2}.$$

3.1.5 Kurtosis

Kurtosis is the fourth statistical moment, normalized by the standard deviation to the fourth power. It is a measure of whether the data are peaked or flat relative to a normal distribution. The noise in the RF spectrum is typically considered to have a normal distribution. The normal distribution has a value of 3.

$$\kappa = \frac{M_4}{\sigma^4}.$$

$$\kappa = \frac{\frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^4}{\sigma^4}.$$

$$\kappa = \frac{1}{N\sigma^4} \sum_{i=1}^N (x_i - \bar{x})^4.$$

3.1.6 Maximum

“Max” is the largest value of a set of numbers.

$$y = \max[x(n)].$$

3.1.7 Minimum

“Min” is the smallest value of a set of numbers.

$$y = \min[x(n)].$$

3.1.8 Median

The statistical median is an order statistic that gives the “middle” value of a set of samples. Median is the middle value of a set of data values that divides the set into 2 groups. Half the groups exist below and half exist above this value.

3.1.9 Rank Order Filter

Rank order filter is a sorting process by which a set of numbers is ordered from the smallest to the largest value. Rank order filtering is a nonlinear filtering technique that orders the contents of a filter kernel and selects the sample indexed by rank from the magnitude ordered samples.

Rank order filtering can be summarized as follows:

$$y = \sum_{i=1}^N a_i \tilde{x}_{(i)}.$$

where $\tilde{x}_{(i)}, i = 1, \dots, N$ is the result of sorting the data in ascending order. With this definition, the max, min, and median can be obtained from a rank order filter as follows²:

Min:

$$y = \sum_{i=1}^N a_i \tilde{x}_{(i)},$$

$$a_i = 1 \text{ for } i = 1,$$

0 otherwise.

Max:

$$y = \sum_{i=1}^N a_i \tilde{x}_{(i)},$$

$$a_i = 1 \text{ for } i = \frac{N}{2},$$

$$0 \text{ otherwise.}$$

Median:

$$y = \sum_{i=1}^N a_i \tilde{x}_{(i)},$$

$$a_i = 1 \text{ for } i = \frac{N}{2},$$

$$0 \text{ otherwise.}$$

3.1.10 Crest Factor (CF)

Crest factor (CF) is a measure of a waveform showing the ratio of peak values to the effective value. In other words, CF indicates how extreme the peaks are in a waveform.

$$Crest\ Factor = \frac{|x|_{peak}}{x_{rms}}.$$

Noise sources are characterized by their CF, which is the peak to average ratio of the noise. In a technical bulletin, XiTRON reported CF values between 5 and 7 for random noise.³ For example, a 5:1 CF of the noise voltage is $20\log 5 = 14$ dB. This is a measure of the quality of the noise distributions and one way to measure its Gaussian nature.⁴ For the purpose of algorithm development, the CF equation was modified as follows:

$$Crest\ Factor = \frac{Max}{Median}.$$

3.1.11 Running Median

To define the running median filter, let $\{x\}$ be a discrete time series. The running median passes a window over the sequence $\{x\}$ that selects, at each instant m , an odd number of samples to comprise the observation vector $x(n)$. The observation window is typically symmetric and centered at n , resulting in

$$x(n) = [x(n - N_1), \dots, x(n), \dots, x(n + N_1)]^T.$$

where N_1 may range in value over the nonnegative integers and $N = 2N_1 + 1$ is the (odd valued) window size. While processing such noncausal observation vectors has traditionally been referred to as smoothing, we loosen the terminology somewhat and refer to the processing of both causal and noncausal observations as simply filtering. The median filter operating on the input sequence $\{x\}$ produces the output sequence $\{y\}$, where at time index n

$$y(n) = MED[x(n)]$$

$$= \text{Median value of } [x(n - N_1), \dots, x(n), \dots, x(n + N_1)].$$

That is, the samples in the observation window are sorted, and the middle, or median, value is taken as the output.⁵

3.2 Statistical Summary

There were 31 different groupings of the RF spectrum data measurements. The number of data files under each of the main groupings was varied. For the purpose of developing the algorithm, only a single data file was selected from each group. Each data file was processed to obtain the following characteristics: RBW, mean, standard deviation, median, max, min, kurtosis, and CF. A summary of the results is in Table 2.

The following results were noted:

- The smaller the RBW, the lower the noise floor. The equation for thermal noise power is $P = kTB$, where B is bandwidth. In this case, the RBW of 1 kHz has the lowest noise value. The RBW of 1 MHz has the highest noise value.
- Each 10-fold increase in bandwidth results in a 10-dB increase in noise power. This relationship is illustrated in this data set.
- The calculated mean and median values are very close for a given RF measurement configuration.
- The CF for noise-only data files was on the order of approximately 10 to 13. Noise-only data files were estimated by visually inspecting the spectrum plot.

Table 2 Statistical analysis of the RF spectrum measurements

4. Morphological Image Processing

A description of a technique for automatically estimating the noise floor spectrum was given at a conference back in 1997.⁶ This technique is based on applying the morphological binary image processing operators to the RF spectrum. The technique works well in both flat and nonflat noise floor spectra. Morphology image processing is a set of nonlinear operations. Ready et al. note that “humans are good at estimating the noise floor spectrum by ‘eyeballing’ a spectral plot. Intuitively, we separate the spectral humps from the noise floor spectrum by eliminating those parts of the spectrum shape that are due to signals and visually draw in the noise floor spectrum.”⁶

Morphology is a broad set of processing techniques that process images based on shapes. Morphological operations apply a structuring element to an input image, creating an output image of the same size. In a morphological operation, the value of each pixel in the output image is based on a comparison of the corresponding pixel in the input image with its neighbors. By choosing the size and shape of the

neighborhood, you can construct a morphological operation that is sensitive to specific shapes in the input image.

4.1 Dilation, Erosion, and Opening

The most basic morphological operations are dilation and erosion. Dilation adds pixels to the boundaries of the objects in an image, while erosion removes pixels on object boundaries. The number of pixels added or removed from the objects in an image depends on the size and shape of the structuring element used to process the image. In the morphological dilation and erosion operations, the state of any given pixel in the output image is determined by applying a rule to the corresponding pixel and its neighbors in the input image. These rules are known as the erosion and dilation:

Erosion:

$$A \ominus B = \bigcap_{b \in B} A_{-b}.$$

Dilation:

$$A \oplus B = \bigcup_{a \in A} B_a.$$

The opening of A by B is obtained by the dilation of A by B , followed by erosion of the resulting structure by B .

Opening:

$$A \circ B = (A \oplus B) \ominus B.$$

The application of the opening technique on the RF spectrum is the basis for noise floor estimation. The estimation of the noise floor is used as a reference level to set a threshold detection level.⁷

In signal, statistical, and image processing, the minimum and maximum operators are typically encountered. Gil and Kimmel note, “In mathematical morphology, the result of such an operator is referred to as the erosion (or dilation) of the signal with a structuring element given by a pulse of width p .”⁸

For the 1-D case, this reduces to a simple filter of just providing the max or min value of a set of values.⁸

1-D max filter: Given a sequence x_0, \dots, x_{n-1} and an integer $p > 1$, compute

$$y_i = \max_{0 \leq j < p} x_{i+j},$$

$$\text{for } i = 0, \dots, n - p.$$

1-D min filter: Given a sequence x_0, \dots, x_{n-1} and an integer $p > 1$, compute

$$y_i = \min_{0 \leq j < p} x_{i+j},$$

for $i = 0, \dots, n - p$.

4.2 Watershed Transformation

In morphology image segmentation, there is a technique called watershed transformation. It has various definitions and implementations. In concept, it partitions an image into disjoint regions so that these regions have the same properties. Imagine a landscape with various hills and valleys. As the area is flooded by water, the low-lying areas will fill up, thus creating a uniform region. Roerdink and Meijster note, “When the water level has reached the highest peak in the landscape, the process is stopped. As a result, the landscape is partitioned into regions or basins separated by dams, called watershed lines.”⁹

There are various implementations of the watershed transformation. The purpose of applying the watershed transformation was to obtain the envelope of the spectral data array. For the spectral data array, the transformation was modified to a highly localized implementation. A search is conducted for 2 adjacent peak amplitudes in the spectral data array. The spectral data values are replaced between the 2 adjacent peak locations with the smaller of the 2 peak amplitude values if the spectral data are less than that value. Figure 1 shows a spectral data file with the modified watershed transform. The red curve is the modified watershed transform curve. The blue curve is the measured spectral data. Figure 2 shows a zoomed-in portion of the spectral data file.

Fig. 1 Spectral data file with modified watershed transform

Fig. 2 Zoomed-in examination of spectral data file with modified watershed transform

5. Algorithm

The algorithm process was developed in MATLAB. Appendix A is the code used to process and generate the enclosed RF spectrum signatures with the corresponding results of the morphological processing and resultant threshold detection level. The following is a description of the detection thresholding level generation based on morphological filter processing:

- 1) Determine the RBW of the spectral data.
- 2) Determine some statistics on the spectral data file: median, max, and CF.
- 3) Starting from the beginning of the spectral data array, determine the first 2 peak amplitude locations and values. Replace the data array between these 2 peak locations with the smallest peak amplitude value if the data value is less than the smallest peak value. Search for the next peak amplitude location and value. Using this location with the last peak location, replace any spectral data value in the valley between the latest 2 peak locations with the smaller amplitude of the 2 peaks. Continue to search and replace until the end of the spectral data array.
- 4) Perform a sliding running median on the envelope spectral data array for a window size of 5. The start and end of the spectral data are somewhat an issue. In this case, the first 5 points used the median value determined at the first valid value. The last 5 points used the median value determined at the last valid point.

- 5) Perform an erosion operation on the median filtered spectral data as computed in step 4. Starting from the lowest-frequency component, create the eroded spectral array with an initial sliding window of size 2. Basically, calculate the minimum value for the given window size, fill in that position, and shift the processing window one position in frequency position to calculate the next value. Continue on across the entire median filtered spectral data array. For the last value, use the previous valid value that is calculated.
- 6) Perform a dilation operation on the eroded spectral array as calculated in step 5. In this case, the calculations are performed starting at the highest frequency and continue to the lowest frequency. Dilation is simply the maximum value in the windowed data set. The initial window size is 2. In this case, the maximum value is determined from the sliding window and creating the dilated spectral array.
- 7) Calculate statistics on the dilated spectral array from step 6: mean, median, max, and CF.
- 8) Repeat the morphological filtering of erosion and dilation on the spectral array by increasing the window size by 1 for every pass. For example, on the second pass, the window size is 3 for the eroding and dilation operations. The erosion and dilation operations are applied to the dilated spectral array from step 6. Repeat this process as long as the CF is greater than 10 and the mean power greater than 0.01 on each pass of the morphological filtering.
- 9) If the CF is not greater than 10, then perform the morphological filtering operations until the average power is greater than 0.01.
- 10) Once the convergence has been met, use the resulting morphological filtered data array (i.e., the dilated spectral array) to form the threshold as follows:

$$Threshold = Morphological\ Filtered\ Spectral\ Array + 25 - 2.9 \times 10 \log_{10} \left(\frac{RBW}{1000} \right)$$

6. Conclusion

In general, this enhanced algorithm works well in determining the detection threshold level.

Appendix B displays the graphs of the morphological processing for each of the selected RF spectrum data files. The red curve is the result of the morphological

processing overlaid on top of the RF spectrum signature. The processing results in a curve that converges to the bottom of the noise components.

Appendix C displays the results of the threshold overlaid on top of the RF spectrum signature. The graphs are intended to provide the reader with a qualitative sense of the effectiveness of the automatic detection threshold generation algorithm. False alarms are reduced with the prefiltering of the modified watershed technique compared with the morphological filtering-only case. The actual processing time and number of iterations through the morphological filtering routine are highly dependent on the RBW and spectral coverage band. A small RBW over a large coverage band requires more time to complete the process. The threshold detection level obtained works well for signals present or noise-only RF spectrum data files. The red curve is the threshold when added to the morphological processed array as shown in Appendix B.

Overall, a visual inspection of the graphs shows that the algorithm works well. The false alarm for the 10-kHz RBW is higher than desired. The threshold parameters can be modified to obtain the desired level of detection versus the false alarm.
